
PART E

1. Consider the following processes with arrival times and burst times:

| Process | Arrival Time | Burst Time |

|-----|-----|-----|

| P1 | 0 | 5 |

| P2 | 1 | 3 |

| P3 | 2 | 6 |

Calculate the average waiting time using First-Come, First-Served (FCFS) scheduling.

ANSWER:-

Q.1)

Process	Arrival Time	Burst Time	CT	TAT	WT
P1	0	5	5	5	0
P2	1	3	8	7	4
P3	2	6	14	12	6

Calculate average waiting time using First-Come, first served (FCFS) scheduling.

Quant chart

Process	P1	P2	P3
Chart	0	5	8 14

$TAT = CT - AT$

$WT = TAT - BT$

$WT = \frac{0 + 4 + 6}{3} = \frac{10}{3} = 3.33$

$WT = 3.33$

2. Consider the following processes with arrival times and burst times:

Process	Arrival Time	Burst Time
P1	0	3
P2	1	5
P3	2	1
P4	3	4

--	--	--

P1	0	3
----	---	---

P2	1	5
----	---	---

P3	2	1
----	---	---

P4	3	4
----	---	---

Calculate the average turnaround time using Shortest Job First (SJF) scheduling.

ANSWER:--

Q.2] SJF

Process	Arrival Time	Burst Time	CT	TAT	WT
P1	0	3	3	3	0
P2	1	5	13	12	7
P3	2	1	4	2	1
P4	3	4	8	5	1

Gantt Chart: [P1 | P3 | P4 | P2]

Chart: 0 3 4 8 13

Avg TAT = $\frac{3+12+2+5}{4} = \frac{22}{4} = 5.5$

Avg TAT = 5.5

4. Consider the following processes with arrival times and burst times, and the time quantum for Round Robin scheduling is 2 units:

Process	Arrival Time	Burst Time

--	--	--

| P1 | 0 | 4 |

| P2 | 1 | 5 |

| P3 | 2 | 2 |

| P4 | 3 | 3 |

Calculate the average turnaround time using Round Robin scheduling.

Consider the following process with arrival times & burst times, & the time quantum for Round Robin scheduling is 2 units.

Process	Arrival Time	Burst Time	Completion Time	TAT	WT
P1	0	4	10	10	6
P2	1	5	15	14	9
P3	2	2	6	4	2
P4	3	3	13	10	7

Calculate avg TAT

[P1 | P2 | P3 | P4 | P1 | P2 | P4 | P2]

0 2 4 6 8 10 12 14 16

$$\text{Avg TAT} = \frac{10 + 14 + 4 + 10}{4}$$
$$= \frac{38}{4} = 9.5$$

5. Consider a program that uses the fork() system call to create a child process. Initially, the parent

process has a variable x with a value of 5. After forking, both the parent and child processes

increment the value of x by 1.

What will be the final values of x in the parent and child processes after the fork() call?

ANSWER:--

When a program uses the fork() system call to create a child process, the parent and child processes each have their own separate memory space. Here's how the variable x behaves:

1. **Initial State:** The parent process has a variable x with a value of 5.
2. **Forking:** When fork() is called, the child process gets a copy of the parent process's memory space, including the value of x.
3. **Post-Fork Execution:**
 - Both the parent and child processes will increment their own copy of x by 1.
 - After incrementing, the parent process will have $x = 6$, and the child process will also have $x = 6$.

Detailed Breakdown:

- **Parent Process:**
 - Before fork(): $x = 5$
 - After fork(), it increments x: $x = 5 + 1 = 6$
- **Child Process:**
 - Receives $x = 5$ from the parent process.
 - After fork(), it increments its own x: $x = 5 + 1 = 6$

Final Values:

- **Parent Process:** $x = 6$
- **Child Process:** $x = 6$

In summary, after the `fork()` call, both the parent and child processes will have their own separate copies of `x`, and both will have the final value of 6.
